

Predicting Fuel Efficiency by Minimizing MAPE with Weighted Least Squares

Leopold Marx

ISDS 7103

October 7th, 2020

1 Introduction

Transportation is critical in modern day society. Nearly everyone uses some sort of transportation daily as an intermediate to go about our lives. In most of America, to get to the places you need in a reasonable amount of time, the most common choice of transportation is the automobile. Vehicles come with various properties including sizes, engines, drive trains, air conditioning, make, year, etc. One of the most important features of an automobile is the cost which includes fuel efficiency.

In this project, we will be trying to predict fuel efficiency based on different properties of 1500 automobiles including the variables listed in Table 1.

Table 1: Available Variables

| Variable | Description |
|----------|---|
| origin | Origin of the car |
| maker | Auto Maker |
| model | Model name |
| yr | Year |
| cyl | Number of Cylinders |
| 2wd | 2=Two wheel drive, 4=Four wheel drive |
| auto | 1 = Automatic, 0 = otherwise |
| p/s | 1 = Power steering, 0 = otherwise |
| a/c | O=Air Conditioning, X = otherwise |
| fro | 1 = Front wheel drive, 0 = otherwise |
| wght | Weight (pounds) |
| disp | Displacement (cubic inches) |
| hp | Horsepower |
| lngh | Length (inches) |
| wdth | Width (inches) |
| wb | Wheel base (inches) |
| reli | Reliability index (from Consumer Reports) |
| fid | Firm identification number |
| dom | yes = U.S. built, no = imported |
| eur | Y = European Model, N = otherwise |
| sales | Sales |
| price | List price (dollars) |
| markup | Estimated mark up (thousands of dollars) |
| mpg | Miles per gallon |

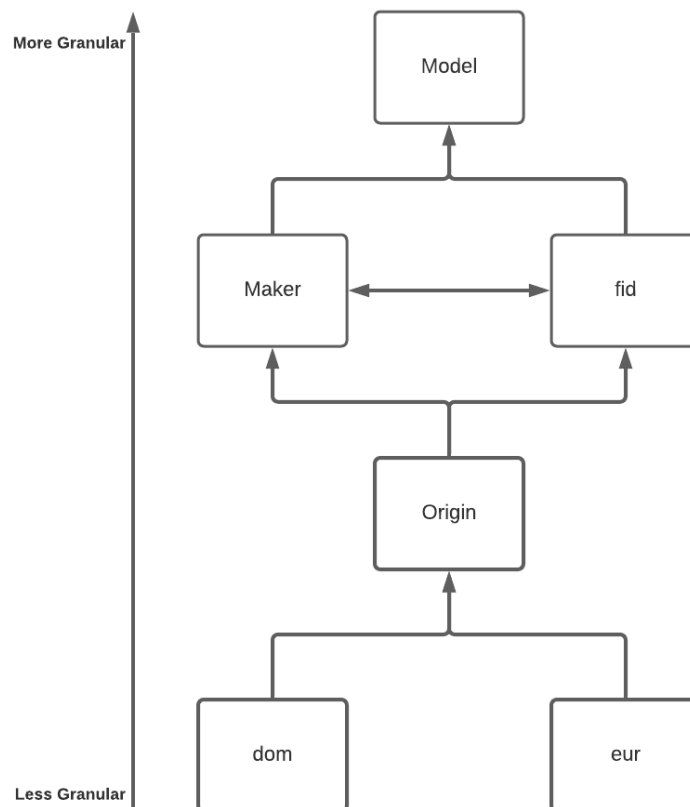

2 Analysis and Methods

2.1 Data Preprocessing

2.1.1 Redundant Categorical Variables

To start off this analysis, we should look at which variables are redundant. One form of redundancy is if any variables are subsets or copies of others. For example, `dom` and `eur` is a subset of `origin`, `origin` is a subset of `maker`, and `maker` is equal to `fid`. This implies that if we use `maker`, then we should not use `fid`, `origin`, `dom`, and `eur` because `maker` already covers all the cases of the subsets. If we use `origin`, we should exclude `maker` because it is a super set and would provide more information that `origin` alone. Similarly if we want to use `dom` and `eur` in our analysis, then we should exclude `maker` and `origin`. See Figure 1 for a visual on which variables are subsets or supersets of others.

Figure 1: Illustration of variable subsets

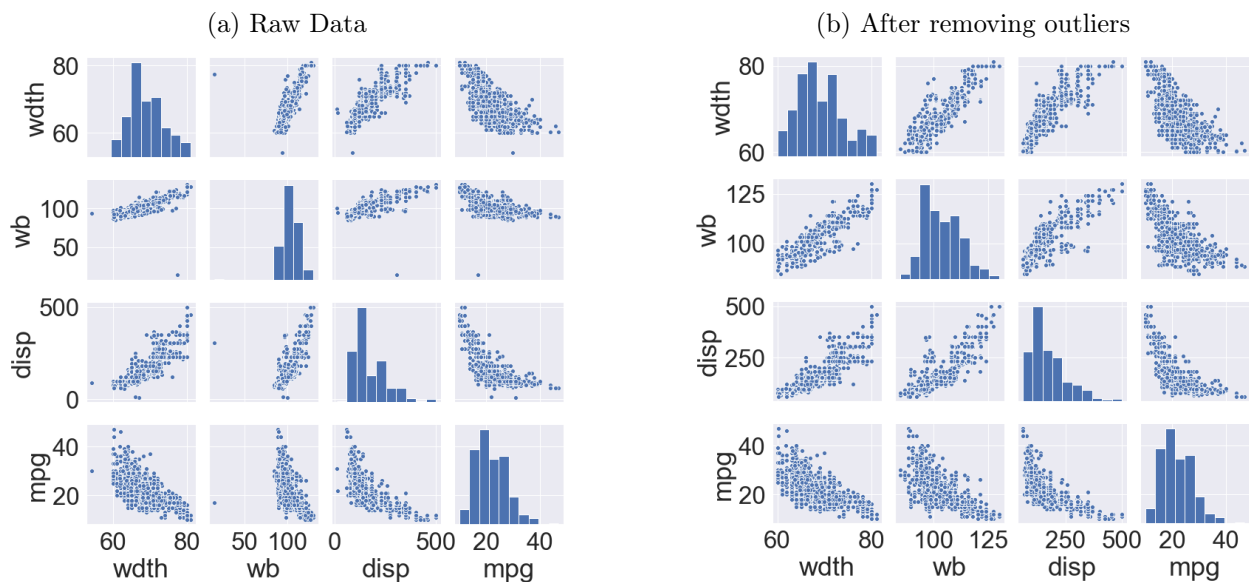

It is to note that `model` is excluded from the analysis because it is too specific of a category for trying to predict fuel efficiency. `model` has 439 unique values which means there

are would only be an average of 3.4 observations per model for 1500 observations. If we were to use `model`, it would likely result in over fitting. It also would likely not necessarily explain the patterns in the data and would probably regurgitate the information in the training set. This model would also be irrelevant if future models of cars are released.

2.1.2 Outliers

In Figure 2, we can see how if we remove a couple outliers for `width`, `wb`, and `disp`, we can drastically improve the understanding of each variable with respect to `mpg`. Observations were removed if `width` was less than 55, `wb` was less than 40, or if `disp` was less than 40. The observations that fell into any of these categories have these id values: 672, 744, 1056, 1462.

Figure 2: Pair Plots Before and After Removing Outliers

In addition to obvious outliers in the pair plots, observations that had large influence from a weighted least squares regression were also removed. More specifically, there was a cluster of observations that had a large Cook's Distance. Observations were removed with these id values: 159, 1166, 1281, 1391, 1392, 1442, 1498, 1499. The total amount of observations removed is 12 which is less than 1% of the original dataset.

2.1.3 Transformations

As we can see in Figure 2 (b) above, the variables in the pair plots are not linear with respect to `mpg`. To improve the linearity and normalcy of variables, a Box-Cox transformation on `wght`, `disp`, `hp`, `length`, `width`, `wb`, `price`, and `markup`. The lambda values that

optimized the Box-Cox transformations for each variable are -0.09466148 , -0.43856908 , -0.20070702 , -0.27736606 , -2.31571202 , -1.64987019 , -0.33435441 , and -0.44343978 respectively. These lambdas are selected by stabilizing variance and minimizing skewness.

2.1.4 Dummy Variables

As seen in Table 1, some of the variables are nominal meaning we need to map them to $n - 1$ binary variables where n is the number of categories. This process would need to be completed for `origin`, `maker`, `a/c`, `fid`, `dom`, and `eur` since there is no definite order to the categories. Keep in mind, this would only need to be done if you want the variable in the model. The $n - 1$ binary variables would more explanation if a car from Japan on average has a higher fuel efficiency rating.

2.1.5 Polynomial Interaction

Because interpretability of the model is not necessarily the goal for this project, we can try to squeeze some more explanation out of the variables by multiply multiplying them together. This also allows the dummy variables to interact with various variables to act like switches to have different weights based on various categories. For example, if cars from the US have better fuel efficiency with the same properties, we can explain that with an interaction.

In my analysis, I found polynomial interaction of orders of 1, 2, and 3 to be sufficient. A polynomial interaction on the order of 3 would return new variables of all polynomial combinations of the variables with less than or equal to 3. For example, a polynomial interaction of x and y on the order of 3 would return $1, x, y, xy, x^2, y^2, x^2y, xy^2, x^3, y^3$.

2.1.6 Train/Test Split

The data set was partitioned into a training and a testing partition. 70% of the samples were placed in the training dataset at random and the remaining 30% was placed in the testing dataset. This is a critical step to make sure the model does not over-fit to the training data. In my modeling, I used the test set as a truly external validation set that allows us to gauge if the model is over fitting the to the data.

2.1.7 Test Set Imputing

The test set was altered by Dr. Chun to simulate imperfect data. Since we need to report a mpg value for each of the observation in the test set, we cannot simply remove these observations. I personally went through each column and checked if there were any anomalies. For example, in the `cyl` column, There were some cells with "acht" cylinders. For those who

do not know German, "acht" means "eight" in English so I mapped this cell to the value 8. Another anomaly I found had to do with spelling. Some values of `maker` and `origin` had misspelled names as well which needed to be fixed.

Another type of anomaly in the test set was missing data. For these observations that had one or more blank rows, I imputed these cells based on the `year`, `model`, `cyl`, and `hp` if available. Through doing some research online, I tried to match the missing value with information I could find online about the automobile.

2.2 Modeling

2.2.1 Objective Function

One of our project requirements is to minimize the mean absolute percent error (MAPE). MAPE is defined as follows:

$$L_{\text{MAPE}}(y, \hat{y}) = \frac{\sum_{i=1}^n \frac{|y_i - \hat{y}_i|}{y_i}}{n} \quad (1)$$

The MAPE loss function differs from most common loss functions, like sums of squared error, by summing the percent error of the true y value. For example a car that has 10 mpg and predicted to have 11 mpg would result in a 10% error. However, if we look at a 50 mpg car predicted to do 45 mpg, there would still be a 10% error. MAPE weights errors based on their true y values unlike least squares where everything is distance based. In other words, sums of squared error treats a 1 mpg error the same no matter what actual mpg value is. MAPE has tighter bounds for lower y values and looser bounds for larger y . This is an appropriate loss function for this problem because the marginal gain of mpg decreases as the fuel efficiency increases.

From my research, minimizing MAPE alone is quite tedious because there has to be non-linear or iterative optimization methods to find the optimal betas for the model. Minimizing sum of squared error would not do a proper job picking the optimal weights for minimizing MAPE. However, if we could weight each error by the true value, we could get pretty close to MAPE. This is where my interest with weighted least squares came to interest. Below is the loss function for weighted least squares:

$$L_{\text{WLS}}(y, \hat{y}) = \sum_{i=1}^n w_i (y_i - \hat{y}_i)^2 \quad (2)$$

If we use $\frac{1}{y_i}$ as w_i in the WLS loss function, we can get pretty close to the loss function of MAPE with the only difference being a squared distance in the numerator instead of the

true distance. Although not exact, this will act quite similarly to how the MAPE objective function operates. It is to note that we can ignore the value of n because it is a constant with respect to the betas. Minimizing $L_{\text{MAPE}} \cdot n$ will also minimize L_{MAPE}

$$L_{\text{MAPE}^*}(y, \hat{y}) = \sum_{i=1}^n \frac{(y_i - \hat{y}_i)^2}{y_i} \quad (3)$$

This small change in the objective function allows us to go from a non-linear optimization to an analytical solution for optimal betas. Using a weighted least squares approach to minimizing MAPE is To use all the powerful regression tools, I will be fitting my model with MAPE* (3) and selecting variables based on minimal MAPE (1).

2.2.2 Variable selection

Variable selection is very important especially when using polynomial interaction that results in several thousand new variables. My algorithm for variable selection is a variant of forward selection. For each potential variable added to the model, I run a 5 fold cross validation. For each fold, I fit the weighted least squares model (which minimizes MAPE*, not MAPE) with the training data from the 4 folds and with the selected variables along with the new candidate. Once the model is fit, then calculate the true MAPE value. The average of the 5 true MAPE values is calculated. Which ever candidate variable has the minimum average MAPE value, it is added to the selected list. This process continues until the steps between average MAPE values is less than 0.00001 or there are no sufficient variables left.

This algorithm is a sound way to rank which variables should be in the model based on minimizing MAPE however, there are some things to note about this algorithm:

- This algorithm only considers variables with significant addition (p value smaller than 0.1)
- Even though the data is being validated through 5 fold cross validation, I found that this selection process alone caused over fitting since every point was used for training and testing. This is why we need a truly external dataset discussed in section 2.1.6.
- Once this algorithm terminates, the test set is used to prune most recently added variables (next section).

2.2.3 Variable Pruning

The variable selection algorithm mentioned above is essentially a ranking of the variables that should be in the model. We still need to find out what is the best subset of variables

that minimizes an external testing dataset. To do this, I plotted the first x variables selected vs the testing MAPE score. Please see Figure 3 for an example.

Figure 3: Number of Variables vs MAPE for Order 2 Polynomial Interaction with **maker**

2.2.4 Finding the Optimal Model

As alluded to in section 2.1.1, we should not be modeling with **maker** and **origin** dummy variables as **origin** is a subset of **maker**. For this reason, I also removed **eur** and **dom** from the analysis as they did not explain much. The choice between choosing **maker**, **origin**, or neither gives us 3 options.

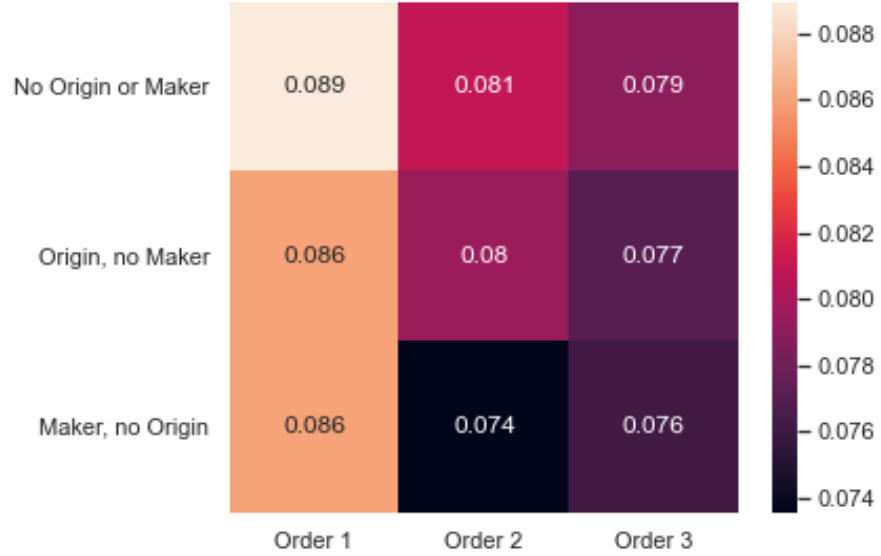

Another dimension of complexity is to change the order of the polynomial interaction. For my analysis, I investigated orders 1 through 3.

For each of these two dimensions, I ran the variable selection and pruning algorithm and got the following testing MAPE scores in Figure 4. Note that Figure 3 is the pruning graph for the optimal option of Maker, no Origin and Order 2 polynomial interaction.

2.2.5 Notable attempts at improving Modeling

- PCA: a PCA transformation on all continuous variables was made and it made testing MAPE worse for all models in contention.
- Factor Analysis: a factor analysis transformation was preformed on all variables and it made testing MAPE worse for all models in contention.

Figure 4: MAPE Test Rate by Polynomial Interactions and Varying Granularity of **maker**

- Gradient Descent: I tried setting up a non-linear optimization model with minimizing MAPE directly by changing the weights for each variable. However, I ran into issues with picking a proper step parameter. Since MAPE had an absolute value in the function, it make gradient descent pretty tricky. I even tried a variant of gradient decent where the weight on the gradient decreases as the number of iterations increases.
- Inverse transformation: initially it looked like a lot of the continuous variables had an inverse relationship. This transformation preformed worse with the same modeling techniques.

3 Conclusion and Summary

Throughout the duration of this project, I found the best model was a weighted least squares model with $w_i = \frac{1}{y_i}$. I variables I used included polynomial interaction on the order of 2 all continuous variables along with the **maker** dummy variables. This model resulted in the parameters listed in Table 4 and a validation MAPE of 7.3582%. Please note that some of these variables have been transformed as per section 2.1.3.

I think it is amazing that with a deeper understanding of the mathematical background of the problem and objective, we can turn a relatively difficult problem and simplify it with some minor approximations.

If I had more time for this project, I would investigate how weights of $\frac{1}{y^2}$ would affect

Table 2: Variable coefficients for Best Model

testing MAPE. For potential different models, I would be tempted to try a neural network or a random forest since interpretability does not mater for this project. However, I am not sure if MAPE can be minimized directly with these models.

Table 3: Summary Statistics of Predicted mpg values for the test dataset with best model

| Statistic | Value |
|--------------------|---------|
| Mean | 21.7161 |
| Median | 21.4429 |
| Standard Deviation | 5.4795 |
| Min | 11.0924 |
| Max | 41.0123 |
